

Domains vs IPs

localhost

"Localhost" refers to the computer you're currently working on. It's essentially a loopback address that points to the machine itself, allowing it to communicate with itself over a network. In technical terms, the IP address for localhost is usually `127.0.0.1` for IPv4, or `::1` for IPv6.

The localhost simply means a server which is running but loopsback to your own system and we can also do like localhost:3000 but also like 127.0.0.1:3000

IP is of two types:

1. IPV4: in which the digits like 10.10.10.10 each number before decimal must be within 0-255 to be called as a IPV4 and it follows 8 bit code eg 0.0.0.0, 255.255.255.255 each is 8 bit in size , and there are limited number of ip address which can exist in the world isme 2^{32} tha

2. IPV6: isme 2^{128} hai

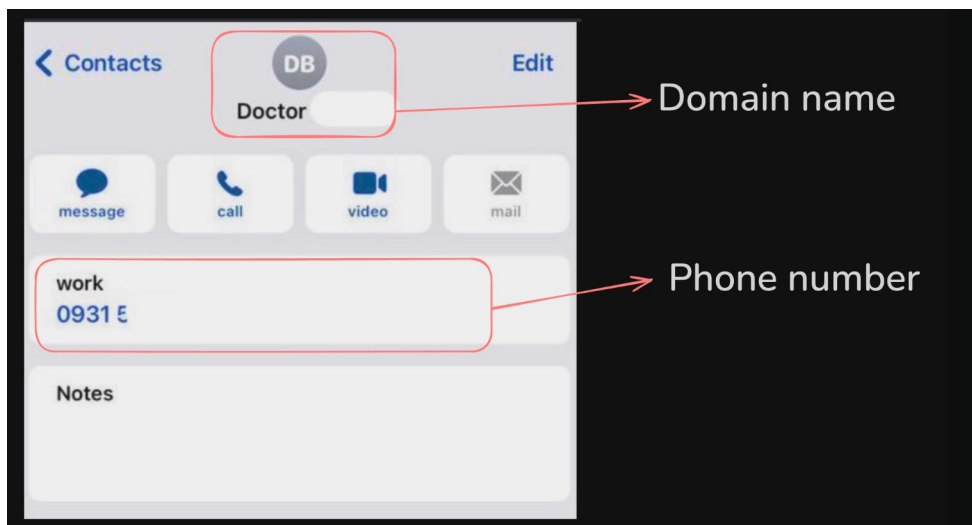

IP (Internet Protocol) Address:

- An **IP address** is a unique string of numbers that identifies a device on a network, like the internet. Think of it like a **house address**: it's how computers (or any devices on the network) know where to send information.
- For example, 192.168.1.1 is an IP address.
- An **IP address** is essential for routing data on the internet, but it's not the most human-friendly system.

Domain name

- A **domain name** is the readable, human-friendly address we use to access websites, like `google.com` or `example.org`.
- Domains are a higher-level abstraction that makes it easier for us to remember websites instead of trying to recall a string of numbers (like an IP address).
- For instance, when you type `www.google.com` into your browser, your computer looks up that domain name and finds the corresponding IP address, then connects to the website.

Domain name vs Phone number

Limited IP addresses

There are limited number of IP addresses in the world (ipv4 specially). So it's not very easy for us to get a public IP. Most IPs are blocked by cloud providers or Big companies (JIO)

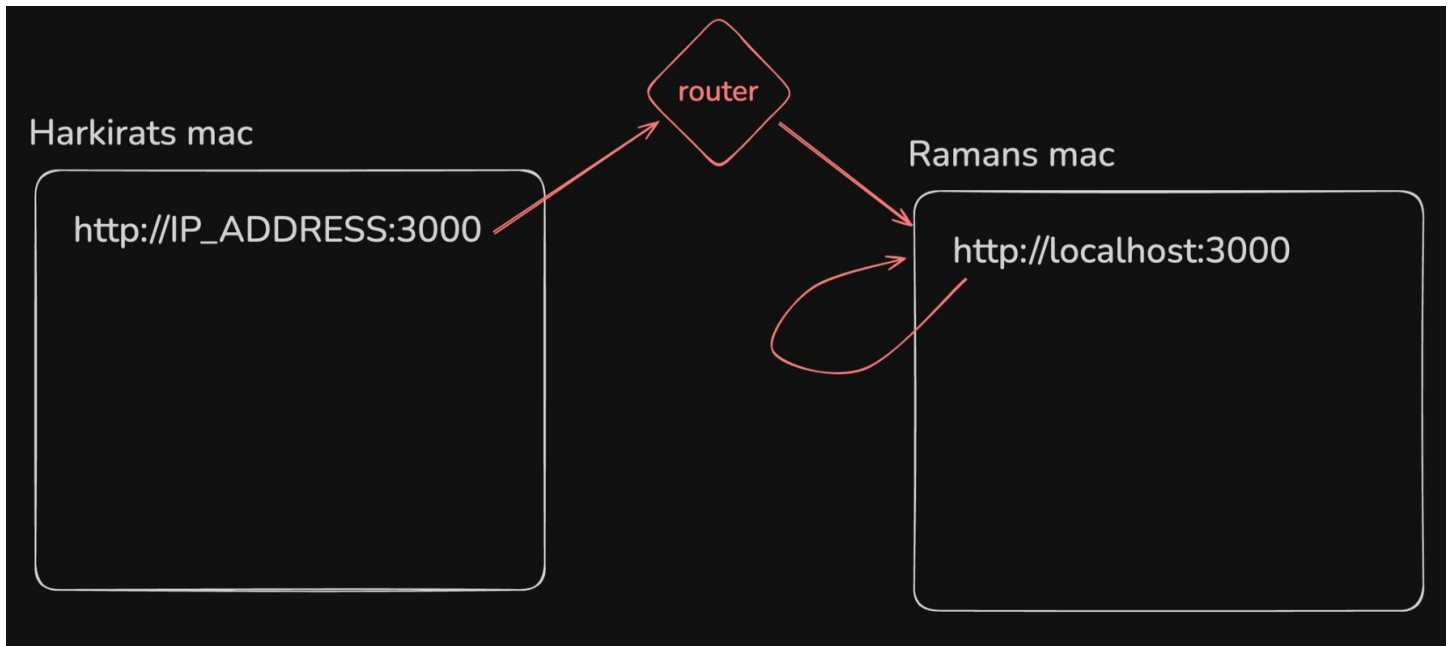

STUN Protocol

It is a protocol that helps devices behind a NAT (Network Address Translation) router discover:

- ✓ Their public IP address
- ✓ The type of NAT they are behind
- ✓ The public port number assigned by the router

Local network, routing (mild hosting)

If you have multiple laptops on the same `wifi` router, you can access one machine from another by using their private IP address. This is a `mild` version of deploying your app on your `local network` (or what's called the `intranet`)

Steps to follow

1. Start a `node.js` process locally on port 3000

```
const express = require('express');
const app = express();
const port = 3000;

app.get('/', (req, res) => {
  res.send('Hello, World!');
});

app.listen(port, () => {
  console.log(`Server is running on <http://localhost>:${port}`);
});
```

1. Find the IP of your machine on the local network

`ifconfig` or `ipconfig`

our you can also use `npx serve`

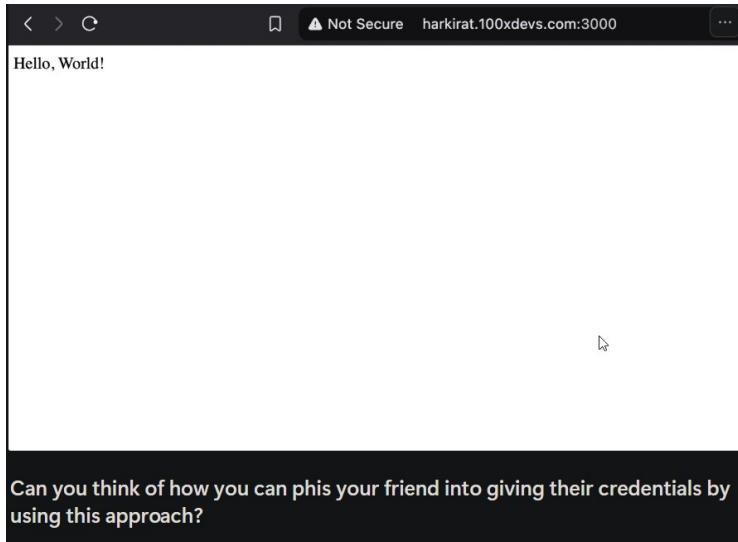

YOU CAN DO A ROUTER SCAN TO GET ALL THE SYSTEM IPS AND THEN GET INTO IT PORT SCAN

HOSTS FILE IMPORTANCE

You can override what your domain name resolves to by overriding the hosts file.

```
vi /etc/hosts
127.0.0.1      harkirat.100xdevs.com
```

you can redirect any website on your machine and then make a same ui and can phish anyone

Baremetal to host postgres servers

What is a VM

VMs run on a physical server (called the **host**) but are abstracted through a layer of virtualization software called a **hypervisor** (e.g., VMware, KVM). This hypervisor divides the host machine's resources (CPU, memory, storage) into separate virtual machines.

Each VM acts like a completely independent machine, even though they share the underlying hardware. You can run different operating systems and applications in different

VMs on the same physical server.

VMs are highly flexible and easy to scale. You can quickly spin up, modify, or delete VMs, and you can consolidate multiple workloads on a single server.

The virtualization layer introduces a slight overhead in terms of performance because the hypervisor needs to manage resources and ensure each VM operates independently. However, with modern hypervisors and powerful hardware, this overhead is minimal.

Bare metal servers(BEST FOR PERFORMANCE)

In a bare-metal setup, an operating system (OS) runs directly on the physical hardware without a hypervisor in between. There's no virtualization layer.

Since there's no hypervisor, bare-metal systems tend to offer better performance, as the OS can directly access all the server's resources without sharing them with other instances. This is especially important for high-performance applications like large databases, gaming servers, or mining crypto

With bare-metal, you're typically limited to the resources (CPU, memory, storage) of the actual physical server. You can't dynamically allocate resources like you can in a VM.

Some servers options:

AWS, GCP, Azure

Easy one: Civo, DigitalOcean, Vultr **SSH protocol, password based auth**

The **SSH protocol** (Secure Shell) is a cryptographic network protocol that allows secure communication between two systems, typically for remote administration. It's most commonly used to log into remote servers and execute commands, but it also facilitates secure file transfers and other operations.

Key Features of SSH:

1. **Encryption:** SSH encrypts the data that's sent between the client and the server, so even if someone intercepts the connection, they can't read the data. This makes it much more secure than older protocols like Telnet or FTP, which transmit data in plaintext.
2. **Authentication:** SSH can use two methods of authentication:
 - **Password-based:** You enter a password to authenticate yourself to the remote system.
 - **Public Key-based:** A more secure method, where the client uses a private key to authenticate, and the server checks it against the corresponding public key. This eliminates the need for passwords and provides an extra layer of security.
3. **Integrity:** SSH ensures the integrity of data, meaning that data cannot be tampered with while it's in transit. If someone tries to alter the data being sent, the connection will be immediately disrupted.

Password based

While setting up a server, select password based authentication

Example from digitalocean

Command to use

```
ssh ubuntu@SERVER_IP
```

or

```
ssh root@SERVER_IP
```

if the system is saying in windows that not enough permissions

then first disable inheritance and then remove the other users from the security tab and also give more permissions to the user such as read , read and write, read and execute

done the problem is fixed

All cloud providers have a different name for their machine

On Digitalocean its called droplets, on aws its called ec2(elastic compute v2)

These website gives two methods to access the machine which is:

1. Passwords based
2. Public key based

The password based approach is easy but there is a problem which is if I have given like access to multiple users and someone does something wrong you wont be able to know that, you may say we can trace there ip but maybe assume he was using a VPN too. So to fix that we use this:

SSH protocol, ssh keypair based (using ssh keys it's a better idea to connect to these vms)

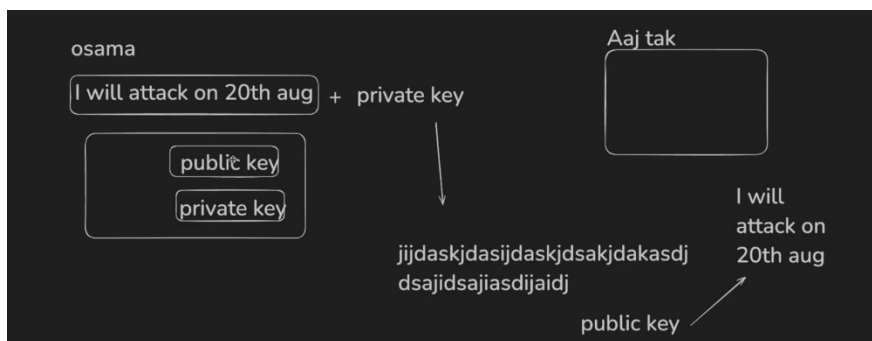

on github also there are two methods to download the repo using ssh or https

things used to create private keys are:

hashing, encryption, public key cryptography, RSA, ed25519, edcdsa

PUBLIC PRIVATE KEY IDEA

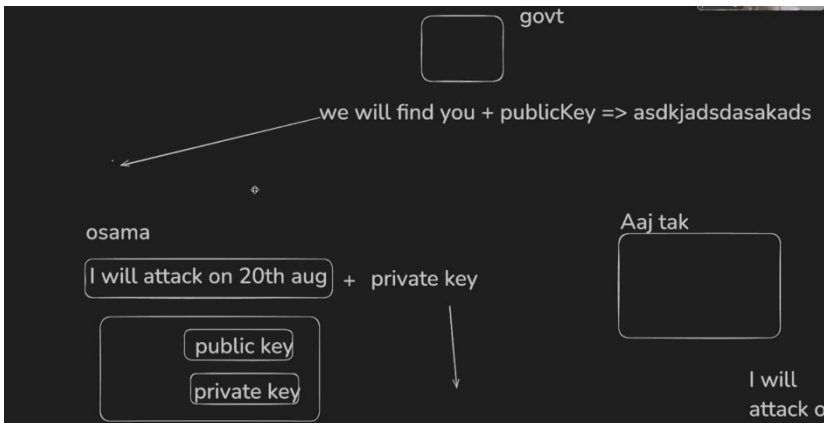

USECASE 1

imagine osama want to broadcast a message, so what he will do first he will send his local public key to everyone and then he will sign the message with his private key

which will return something random gibberish and that gibberish can only be decoded using his public key and then they can identify the message and also this confirms that the msg was sent from osama only

USECASE 2

now if govt want to send some secret message to osama like we will find you they have to sign it using osama publicKey and then osama receives that only he can retrieve the text they sent with his private key no one else can't

to connect to DO(digitalocean) we have to first add a ramans public key in the DO to give access to raman and when raman tries to connect he can connect and DO will check his private key if it matches it will simply let him connect

and if he does something bad we will get to know that

```

+ ~ cd /Users/harkiratsingh/.ssh/
+ .ssh ls
[id_ed25519] [id_ed25519.pub] [id_rsa] [id_rsa.pub] [id_rsa2] [id_rsa2.pub] [known_hosts] [known_hosts.old]
+ .ssh id_rsa2.pub
+ .ssh ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/Users/harkiratsingh/.ssh/id_rsa): /Users/harkiratsingh/.ssh/id_rsa3
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /Users/harkiratsingh/.ssh/id_rsa3
Your public key has been saved in /Users/harkiratsingh/.ssh/id_rsa3.pub
The key fingerprint is:
SHA256:7qsfmKDsHsCEksh9rT7098G3cy6A4gMiHoCVP2hwIa0 harkiratsingh@harkirats-MacBook-Pro-2.local
The key's randomart image is:
+---[RSA 3072]-----+
|..o
|..
|=*o
|Eoo.o.
|=. . . S
|o+ . o +.
|+.o . +o..
|.o..* +.oo..
|o+ .o*o .,
+---[SHA256]-----+
+ .ssh ls
[id_ed25519] [id_ed25519.pub] [id_rsa] [id_rsa.pub] [id_rsa2] [id_rsa2.pub] [id_rsa3] [id_rsa3.pub] [known_hosts] [known_hosts.old]
+ .ssh 123random
+ .ssh
  
```

while creating a public private key we can also add a top level password to secure it more if someone copies that file then he has to enter that password also to access the keys

how to create a public

private key show above?

1. ssh-keygen
2. choose a location and then set up a password

Explore your public and private key

for windows C://users//.ssh//authorized_keys

the pub is the public key and the normal one is the private key

```
cat ~/.ssh/id_rsa.pub
```

```
cat ~/.ssh/id_rsa
```

- Try adding it to Github so you can push to github without password
- Try adding it to digitalocean and ssh using it.

```
ssh ubuntu@IP
```

or

```
git clone git@github.com:100xdevs-cohort-3/week-24-deposit-with-infra.git (try a private repo)
```

```
→ test-app-123 ssh root@146.190.221.189
Enter passphrase for key '/Users/harkiratsingh/.ssh/id_rsa':
Enter passphrase for key '/Users/harkiratsingh/.ssh/id_rsa':
Enter passphrase for key '/Users/harkiratsingh/.ssh/id_rsa':
Welcome to Ubuntu 24.10 (GNU/Linux 6.11.0-9-generic x86_64)

* Documentation:  https://help.ubuntu.com
* Management:    https://landscape.canonical.com
* Support:       https://ubuntu.com/pro

System information as of Sat Jan 25 14:06:06 UTC 2025

System load:  0.0          Processes:    116
Usage of /:   1.6% of 115.25GB  Users logged in:  0
Memory usage: 5%          IPv4 address for eth0: 146.190.221.189
Swap usage:  0%           IPv4 address for eth0: 10.10.0.5

95 updates can be applied immediately.
35 of these updates are standard security updates.
To see these additional updates run: apt list --upgradable

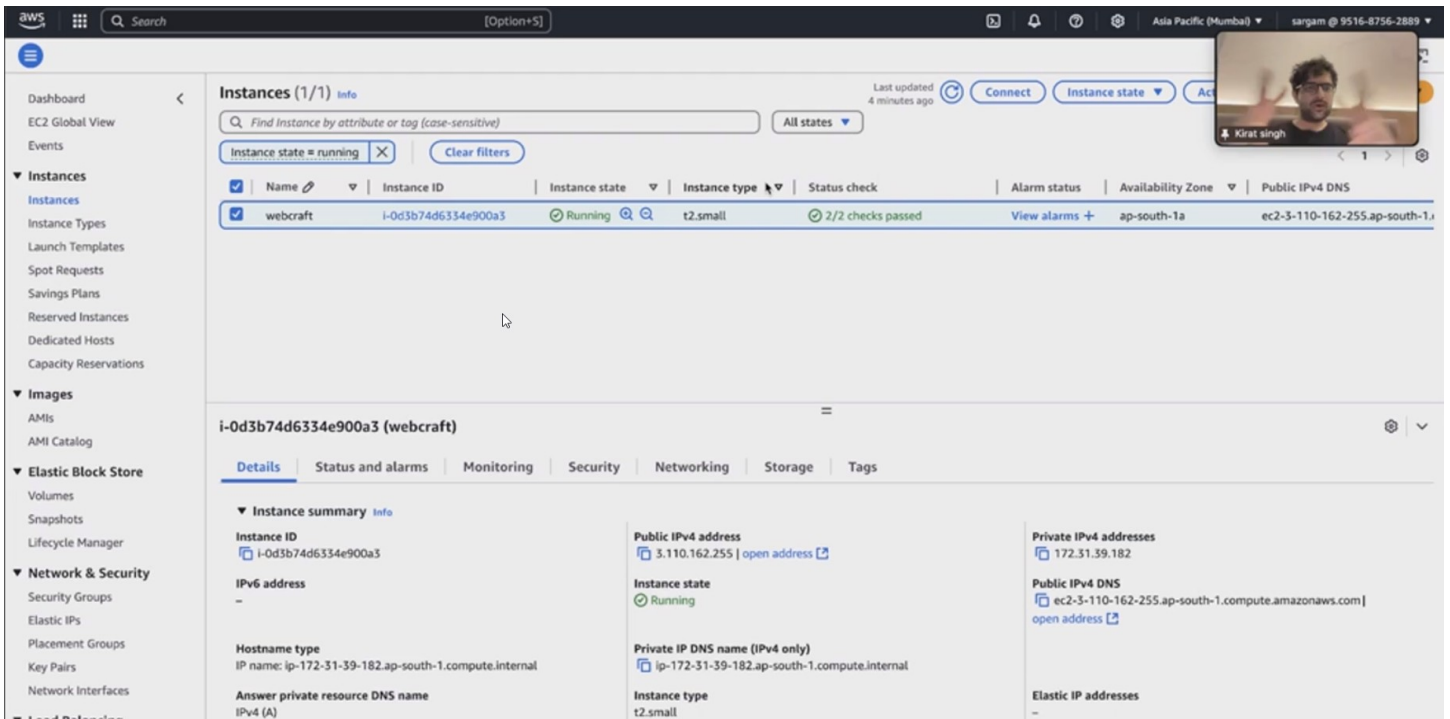

Last login: Sat Jan 25 14:00:39 2025 from 106.219.121.16
root@backend-1:~#
```

Check authorized_keys

NOW IN GITHUB YOU CAN ADD THE PUBLIC KEY AND THEN YOU CAN CLONE THE REPO USING SSH ALSO AND ALSO IN DO YOU CAN CHOOSE SSH KEY OPTION AND THEN ADD THE SSH PUBLIC KEY AND THEN WHEN YOU TRY TO ACCESS THAT MACHINE YOU NEED TO PUT YOUR PASSWORD PHRASE AND THEN YOU CAN USE THE MACHINE AND INSIDE THE VM MACHINE THERE IS JUST A FOLDER NAME **AUTHORIZED_KEYS** WHICH CONTAIN YOUR PUBLIC KEY AND THAT'S WHY IT LET YOU ENTER AND FOR ANYONE ELSE YOU WANT TO ADD YOU CAN JUST PASTE HIS IP

SETTING UP AWS

elastic net = a ip assigned which will remain same even when we restart the system

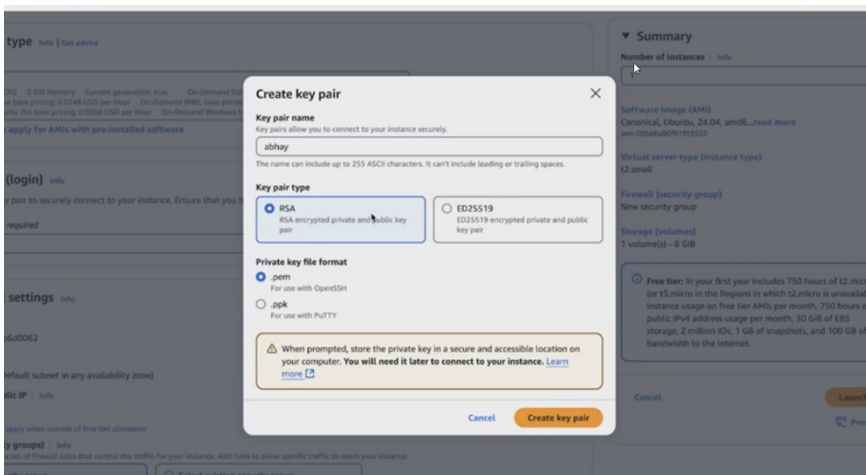

To setup first go to login and then

Search for ec2

Then launch instance

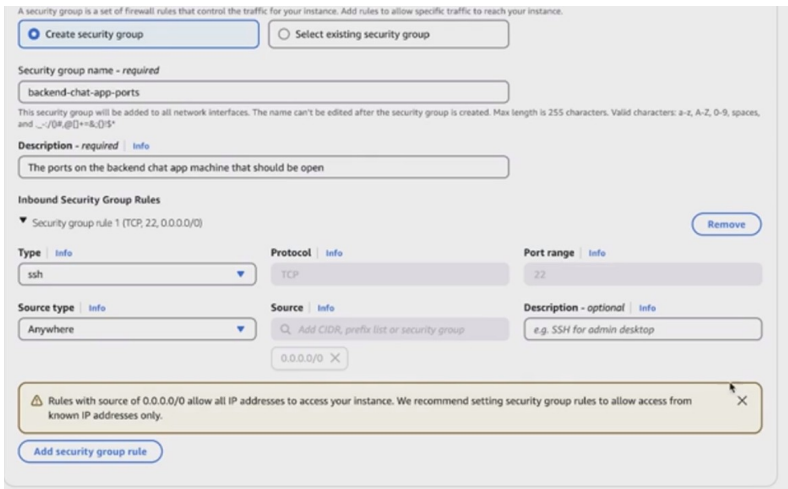

SOME JARGONS C GROUP, JUDGE 0

T2small and t2 micro has a issue that when I will do npm run dev it can go out of memory issue but you can do npm serve

this helps to give access to new member and also the rsa and ed is a algo which helps to make a public and private key.

In do and vulter there is a **firewall** and in aws there is a **security groups**

c group = its like limiting resources to the user based on there usage

type is like when we want to use express, http we use like ssh,

port range this we use when we like require to run multiple backend and frontend

Source type = kaha sae request allowed hona chaiye

SUBNET = bunch of ip ranges used in source type

Security group help us do that thing by securing the ports and all

Different instance types have different usecase like some may be better for video transcoding other maybe better for other reason

NETWORK SETTINGS SECURITY GROUP IS VERY IMPORTANT

1. gave my VM a name
2. Selected the OS
3. Selected the OS version
4. Selected the Instance type
5. Created a new keypair, set it
6. Added a new sec group, opened port 3000 and 22
7. Add 16 gb storage

to to use the

ssh [ubuntu@ip](#)

chmod 400 pdkey.pem (DO IN GITBASH)

[ssh -i pdkey.pem ubuntu@16.170.98.95](#)

ssh -i abhay.pem [ubuntu@ip](#)

```
RWE
```

```
110=>6
```

```
100=>4
```

```
100=>4
```

RWE = read , write, execute

first person has read and write access

second and third only read

chmod 700 kirat-class.pem

in this the 700 means the owner should have all the perms

so it gives all the access to the file to the user

after this we can run the ssh command

then in the terminal of the system do the

git clone and npm install commands to install the node

also then just npm install

and then run the node filename

but the problem is we opened the port 3000 and 22 but we can change that in the security option

now we can use the ip to run the server yuhuu we did it

ec2 machines are mostly used for deploying backend so yaa

nginx ≡ is said like enginex its same like apache, haproxy, traffic,

why do we need this?

We have a ugly url like 44.44.42.21:8080

so to remove this type of url we need to use **NGINX**

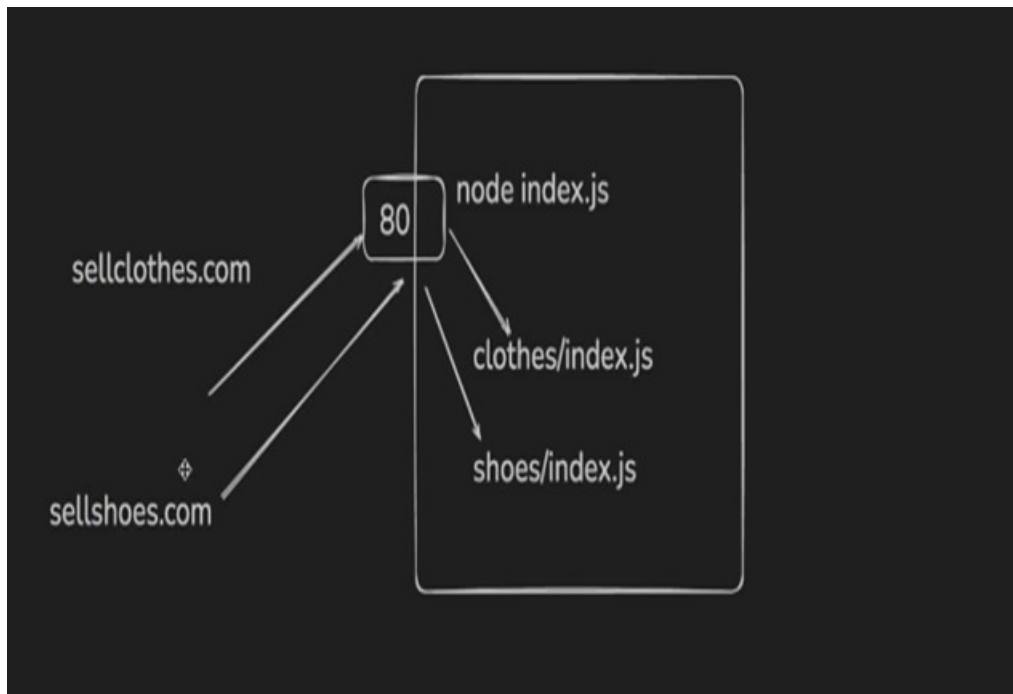

domain the amazon also gives but the :8080 is still there to remove that we use this

if at starting there is https means that is 443 so google has that but the amazon one does not and for that it shows the not secured thingy

for http its 80

so to fix this temp we can run it on port 80

BUT WE CANNOT RUN ON 80

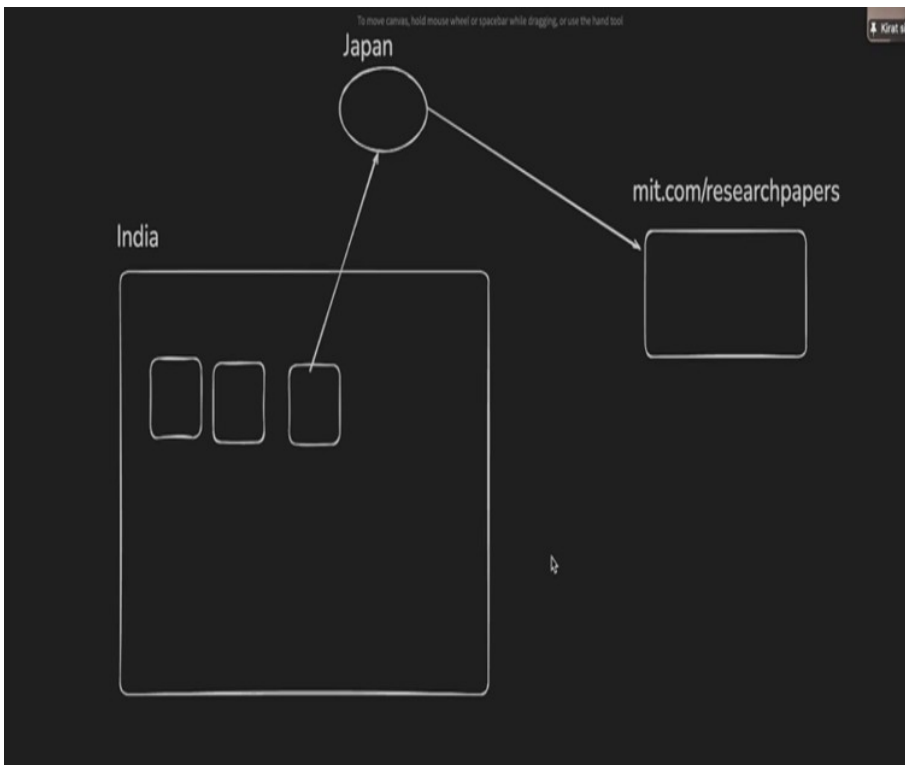

now the issue I s we want that on port 80 if someone comes for sellclothes.com it should take the clothes/index.js and someone comes for sellshoes.com it

should go to shoes/index.js

so for that we need nginx

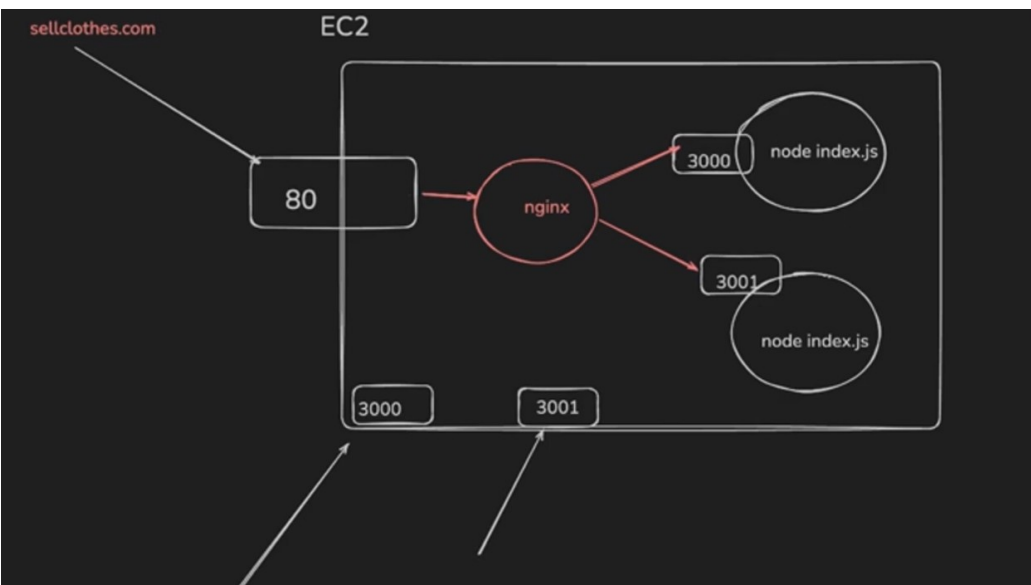

THIS IS CALLED AS REVERSE PROXY

this is how proxy works same like vpn we are trying to access like mit website but imagine they have blocked other users so you try to connect to some authorized servers which will let us connect to the website.

This is called as forward proxy

WHAT IS REVERSE PROXY?

Proxy is like in which we hit the server and then through the server we hit the site

Client → Proxy → Internet Server

Client → Reverse Proxy → Backend Server

but in this when we hit the website the server itself decides that to which port to transfer the request this based on the request is called as reverse proxy

there is something like **load balancer**

PROXY

You don't talk to the website directly.

You talk to a middleman, and the middleman talks to the website.

REVERSE PROXY

You think you are talking to one website, but actually there is a middleman sending your request to different servers.

When you add a ip in a record it takes some time to expand its dns across the world and area and then starts to work

you can check it using **ping url** this nginx helps in using same backend for two websites

sudo == super user do

```
events {
    # Event directives...
}

http {
    server {
        listen 80;
        server_name clothesapp.100xdevs.com;

        location / {
            proxy_pass http://localhost:8080;
            proxy_http_version 1.1;
            proxy_set_header Upgrade $http_upgrade;
            proxy_set_header Connection 'upgrade';
            proxy_set_header Host $host;
            proxy_cache_bypass $http_upgrade;
        }
    }

    server {
        listen 80;
        server_name shoesapp.100xdevs.com;
        location / {
            proxy_pass http://localhost:8081;
            proxy_http_version 1.1;
            proxy_set_header Upgrade $http_upgrade;
            proxy_set_header Connection 'upgrade';
        }
    }
}
```

now after making the urls routes to the ip you have to setup the nginx config

this is like running multiple projects on same server

like when the req comes on 80 from

clothespp it will redirect to 8080 url and other same also

in future if you want to add more you have to create same file in this like the top one

to edit use `sudo vi /etc/nginx/nginx.conf`

then do `sudo nginx -s reload`

80 is for http

443 is for https

and we don't need to open the 8080 , 8081 port also

the nginx will do it itself

WHAT IS LOAD BALANCER?

Its like you have to push a update without closing the app what you do is

you send the code in the m2 and then you start to close the older machine and put them with new code below and then transfer the traffic

to the new machine and then do this again and again

its like down size the old code and upscaling the new code

take code from here for nginx

<https://projects.100xdevs.com/tracks/g0AcDSPL74nk45ZZjRdU/aws-7>

To install node

<https://www.digitalocean.com/community/tutorials/how-to-install-node-js-on-ubuntu-20-04>

to make this work need to open these ports also

The screenshot shows the AWS Management Console interface. The top navigation bar includes the AWS logo, a search bar, and the user's profile. The main content area is titled 'Instances (1/2) info' and displays a table of EC2 instances. The table has columns for Name, Instance ID, Instance state, Instance type, Status check, Alarm status, Availability Zone, Public IPv4 DNS, Public IPv4 address, Elastic IP, and IPv6 IPs. Two instances are listed: 'prod' (i-Oea1f65e1135f7559) and 'dev' (i-062a2d77a5ef66bb3), both in a 'Running' state. Below the table, the 'Security' tab is selected for the 'prod' instance, showing 'Security details' including IAM role, Security groups, and Inbound rules. The 'Inbound rules' table lists three rules: one for port 443 (TCP), one for port 22 (TCP), and one for port 80 (TCP), all associated with the 'launch-wizard-5' security group.

Name	Instance ID	Instance state	Instance type	Status check	Alarm status	Availability Zone	Public IPv4 DNS	Public IPv4 ...	Elastic IP	IPv6 IPs
prod	i-Oea1f65e1135f7559	Running	t3.micro	3/3 checks passed	View alarms +	eu-north-1b	ec2-13-48-10-208.eu-n...	13.48.10.208	-	-
dev	i-062a2d77a5ef66bb3	Running	t3.micro	3/3 checks passed	View alarms +	eu-north-1a	ec2-13-63-158-254.eu-...	13.63.158.254	-	-

Name	Security group rule ID	Port range	Protocol	Source	Security groups	Description
-	sgr-080e29a2b233edc22	443	TCP	0.0.0.0/0	launch-wizard-5	-
-	sgr-07e9a9be65e157654	22	TCP	0.0.0.0/0	launch-wizard-5	-
-	sgr-0ba068f094be8a500	80	TCP	0.0.0.0/0	launch-wizard-5	-

BY CLICKING ON THE LAUNCH WIZARD YOU HAVE TO ADD THE 3000, 3001, 3002 PORT TO MAKE IT WORK ON THE URL OTHERWISE THE MACHINE URL+ THE PORT WILL NOT WORK

you can check dns using

check dns propagation

click on the security group to open the page and then add the inbound security rules

<http://staging.week-25->

[http.pallabdass.me](http://pallabdass.me):3000,3001,3002

The screenshot shows the Google Domains DNS management interface for the domain 100xdevs.com. The left sidebar contains navigation options: All my domains, Domain overview, Registration settings, DNS (highlighted), Website, Reports, Email, and Security. The main content area displays two DNS records:

Record Name	Type	TTL	Value
whatbot	A	3600	18.209.201.135
sumserverclass	A	3600	18.209.201.135

Below the records, there is a "Create new record" link and a "Required Informational-only records" section. At the bottom right, there are "Cancel" and "Save" buttons.

```
ubuntu@ip-172-31-92-166:~/test/sum-server$ sudo vi /etc/nginx/nginx.conf
ubuntu@ip-172-31-92-166:~/test/sum-server$ sudo certbot --nginx
Saving debug log to /var/log/letsencrypt/letsencrypt.log

Which names would you like to activate HTTPS for?
We recommend selecting either all domains, or all domains in a VirtualHost/server block.
