

# JS Architecture

## Node.js

↳ Its a JS runtime

JS can run in

- Browser
- data centers
- Flight TV
- Mobile devices

→ Single Threaded

- ↳ Using single core single executor nonhelpers
- ↳ Async in nature
- ↳ use callbacks

Typical task goes on while other tasks can be done parallelly.

Interpreted → line by line (start)

loosely typed → no need to define int, var etc.

HTML stuffs

↳ contain local storage inside browser

F12 → Application → Local Storage

write a backend server that on / route → Points sum  
20/10

## Synchronous code

- ↳ Just calling the function simply and using
- ↳ executed line by line in order its written each operation waits for previous one to complete before moving to next one.

## I/O heavy operations

↳ refers to heavy tasks in a computer program that involves a lot of data transfer btw program and external devices.

↳ waiting for data to be read from sources like disks, networks, databases which is time consuming.

eg

↳ Reading from file

↳ starting a clock

↳ HTTP requests (Hyper-text transfer Protocol req)

fs → file system library

↳ readfile

↳ readfile sync

## CPU Bound tasks

Operations that are limited to speed and power of the CPU. require processing power

## I/O Bound tasks

Op that are limited by system I/O capabilities, such as disk I/O, network I/O or other data transfer. Spend time in waiting for I/O operations.  
eg → read file

one by one X

content switch btw them ✓

↳ Runs Parallely: which is done early then prints.

## Functional arguments

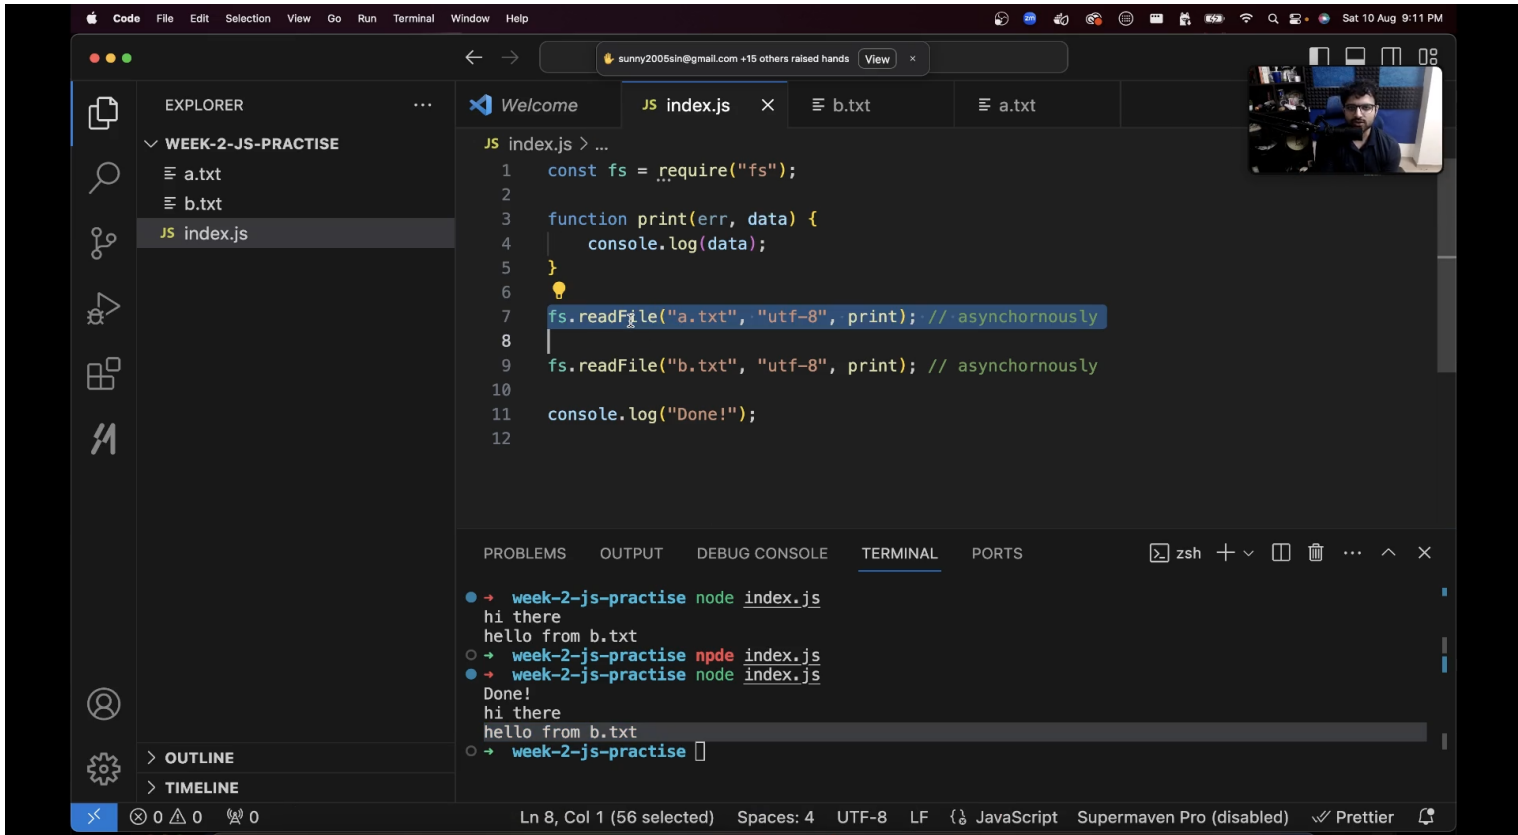

↳ Passing a ( ) to another ( ) as an argument

```
function doOperation(a, b, op) {  
  return op(a, b)  
}
```

console.log(doOperation(1, 2, sum))

# Async code, callbacks

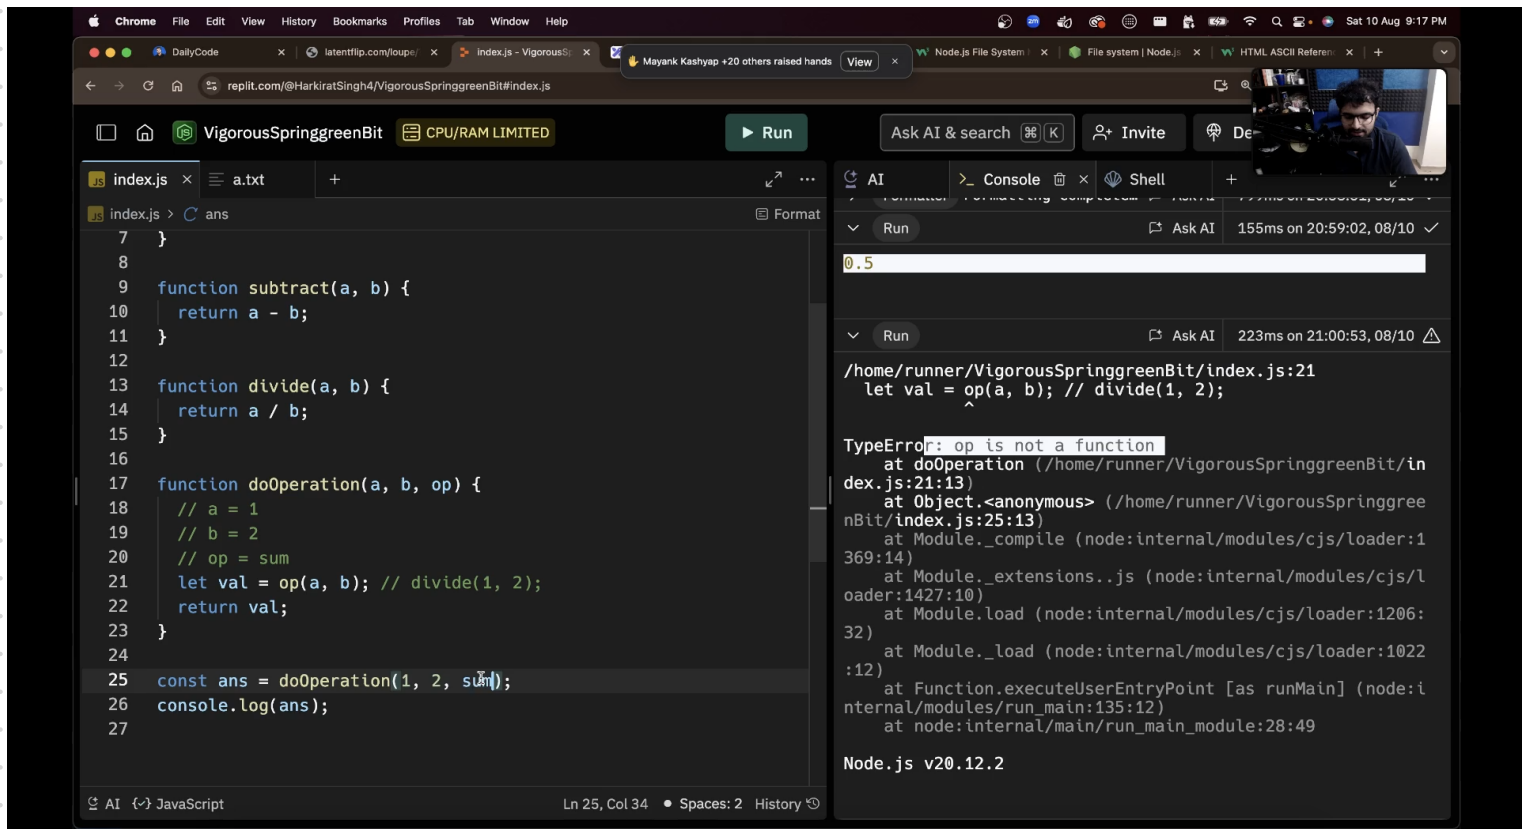

↳ Not waiting for finish move to next on

```
1 const fs = require("fs");
2
3 function print(err, data) {
4   console.log(data);
5 }
6
7 fs.readFile("a.txt", "utf-8", print); // asynchronously
8
9 fs.readFile("b.txt", "utf-8", print); // asynchronously
10
11 console.log("Done!");
12
```

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL PORTS

```
• → week-2-js-practise node index.js
hi there
hello from b.txt
○ → week-2-js-practise node index.js
• → week-2-js-practise node index.js
Done!
hi there
hello from b.txt
○ → week-2-js-practise
```

```
7 }
8
9 function subtract(a, b) {
10   return a - b;
11 }
12
13 function divide(a, b) {
14   return a / b;
15 }
16
17 function doOperation(a, b, op) {
18   // a = 1
19   // b = 2
20   // op = sum
21   let val = op(a, b); // divide(1, 2);
22   return val;
23 }
24
25 const ans = doOperation(1, 2, sum);
26 console.log(ans);
27
```

Run

```
0.5
```

Run

```
/home/runner/VigorousSpringgreenBit/index.js:21
let val = op(a, b); // divide(1, 2);
          ^
TypeError: op is not a function

Node.js v20.12.2
```

```

JS index.js > print
1  const fs = require("fs");
2
3  function print(err, data) {
4      if (err) {
5          console.log("File not found!");
6      } else {
7          console.log(data);
8      }
9  }
10
11 fs.readFile("aas.txt", "utf-8", print); // asynchronously
12
13 // fs.readFile("b.txt", "utf-8", print); // asynchronously
14

```

ad here = sunna padega

set Timeout  
↳ async

readfileSync → will stay

```

function timeout() {
  console.log("Click the button!");
}

console.log("Hi!");

setTimeout(timeout, 1000);

console.log("Welcome to loupe.");

let c = 0;
// 3-4s
for (let i = 0; i < 10000000000; i++) {
  c = c + 1;
}

console.log("Expensive operation done");

```

→ Hi  
→ welcome to loupe  
→ exp o p  
→ click the button  
Boom!!!

eg  
↳ Washing Machine  
10 mins Beep

Running a treadmill  
30 minutes  
without completing  
you will go??  
NO Right 😊

If anything or something happening in call stack the code will wait until it is completed

↳ (web APIs, callback queue)

WebAPIs → Async (?)

↳ washing machine

When the call stack is free the data which was finished from web APIs and was sent to callback queue now can be printed. (You can see in loop)

for reading data use

↳ async code

# Classes in JS

## Primitive

↳ number

↳ string

↳ Boolean

## Complex types

↳ Objects

↳ Arrays

## Date Class

↳ `const date = new Date();`

`console.log(date);`

↳ `date.getFullYear();`

## Promise class

↳ Promise class gives you a promise that I will return u something in the future

Two approaches

Callback based approach

Promise based approach

Promise in JS is an object that represents the **eventual completion** (or failure) of an async operation and its resulting value.

Callback code

```
function main() {
```

```
}
```

```
setTimeout(main, 3000)
```

callback

Promises (more cleaner code)

↳ need this due to callback hell

↳ superior way to write callback

```
setTimeoutPromisified(3000)
```

```
then(callback)
```

Promise returns object of the Promise class

```
function setTimeoutPromisified(ms) {
```

```
  const d = new Promise();  
  return d;  
}
```

```
}
```

```
let p = setTimeoutPromisified(5000);
```

```
console.log(p);
```

```
function waitFor3S(resolve) { // resolve = main  
  setTimeout(resolve, 3000)  
}
```

```
function main() {  
  console.log("main is called")  
}
```

```
waitFor3S(main);
```

O/P → main is called

```
function waitFor3S(resolve) {  
  setTimeout(resolve, 10000)  
}
```

```
function setTimeoutPromisified() {  
  return new Promise(waitFor3S);  
}
```

```
function main() {  
  console.log("main is called")  
}
```

```
setTimeoutPromisified().then(main); // promise based approach
```

O/P → main is called

Promise takes one () as a input iss () ka job phela argument hoga whenever its called uske baad i will call whatever is passed in a then (main)

Promise → random → resolve → data  
()            ()            ()

↳ Yeah complete hoga fir next kaam hoga

```
function random(resolve) { // resolve is also a function
  resolve();
}

let p = new Promise(random); // supposed to return u something eventually

// using the eventual value returned by the promise
function callback() {
  console.log("promise succeeded");
}

p.then(callback);
```

O/P → promise succeeded  
 Promise → random → resolve  
 then ← resolve ← resolve  
 nae finish  
 callback → Print hua  
 RO call kara

```
function random(resolve) { // resolve is also a function
  setTimeout(resolve, 3000);
}

let p = new Promise(random); // supposed to return u something eventually

// using the eventual value returned by the promise
function callback() {
  console.log("promise succeeded");
}

p.then(callback);
```

O/P → after 3sec

## Promises

Whatever is passed to first argument of Promise class, wka job first argument hai, whenever that called, .then (callback), this will be called

```
const fs = require("fs");

function readTheFile(sendTheFinalValueHere) {
  fs.readFile("a.txt", "utf-8", function(err, data) {
    sendTheFinalValueHere(data);
  });
}

function readFile(fileName) {
  // read the file and return its value
  return new Promise(readTheFile);
}

const p = readFile();

function callback(contents) {
  console.log(contents);
}

p.then(callback)
```

```

const fs = require("fs");

console.log("-----top of the file-----");

function readTheFile(resolve) {
  console.log("readTheFile called");
  setTimeout(function() {
    console.log("callback based setTimeout
    completed");
    resolve();
  }, 3000);
}

function setTimeoutPromisified(fileName) {
  console.log("setTimeoutPromisified called");
  // read the file and return its value
  return new Promise(readTheFile);
}

const p = setTimeoutPromisified();

function callback() {
  console.log("timer is done");
}

p.then(callback)

console.log("-----end of the file-----")

```

washing machine

```

→ week-2-js-practise node index.js
-----top of the file-----
setTimeoutPromisified called
readTheFile called
-----end of the file-----
callback based setTimeout completed
timer is done

```

```

function setTimeoutPromisified(time) {
  return new Promise(function () {
    setTimeout(resolve, time);
  });
}

function callback() {
  console.log("Time has passed")
}

const p = setTimeoutPromisified(10000)
p.then(callback);

```

Callback based

fs.readFile("a.txt", "utf-8",  
fn)

Promise based

fs.readFile("a.txt", "utf-8").  
then(fn)

Npm modules should not be send to other just have package.json and then run

↳ npm install

Commander

↳ used to make code more pretty by giving description

↳ node no-ofwords.js -h

↳

↳ Shows all the functions used with name and()

```
const fs = require('fs');
const { Command } = require('commander');
const program = new Command();
program
  .name('counter')
  .description('CLI to do file based tasks')
  .version('0.8.0');
program.command('count') //command name
  .description('Count the number of words in a file')
  .argument('<file>', 'file to count')
  .action((file) => {
    fs.readFile(file, 'utf8', (err, data) => {
      if (err) {
        console.log(err);
      } else {
        const words = data.split(' ').length;
        console.log(`There are ${words} words in ${file}`);
      }
    });
  });
```

```
program.command('count_sentences') //command name
  .description('Count the number of lines in a file')
  .argument('<file>', 'file to count')
  .action((file) => {
    fs.readFile(file, 'utf8', (err, data) => {
      if (err) {
        console.log(err);
      } else {
        const lines = data.split('\n').length;
        console.log(`There are ${lines - 1} lines in ${file}`);
      }
    });
  });
program.parse();
```

↳ node commander.js count dot.txt

↳ mainly used due to -h capability

↳ 2

```
const fs = require("fs");

function main(fileName) {
  fs.readFile(fileName, "utf-8", function(err, data) {
    // hello world
    let total = 0;
    for (let i = 0; i < data.length; i++) {
      if (data[i] === " ") {
        total++;
      }
    }
    console.log(total + 1);
  })
}

main(process.argv[2]); // node index.js
```

↳ data, b text  
It's the location

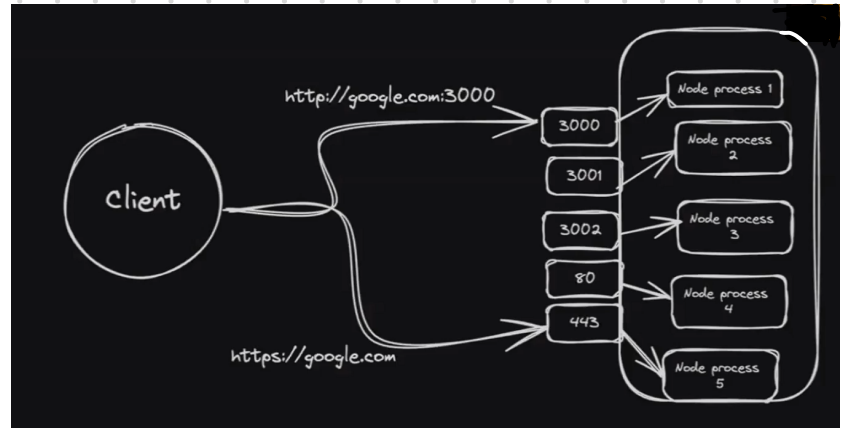

212.2.242.58: (443) → Port

## Ports

↳ Logical endpoints used by protocols to identify specific processes running on a computer or server.

↳ They help direct network traffic to correct application or service on a system.  
Single VM per multiple websites can run

VM: 22.11.44.33

22.11.44.33:3001 → 3001

22.11.44.33:3002 → 3002

22.11.44.33:3003 → 3003

projects.com

app.com

look.com

Most websites are deployed on 443.

## Methods

CRUD

Create → POST

Read → GET

Update → PUT

Delete → DELETE

It's used to specify the type of action that the client wants to perform on a resource on the server.

If url starts with https then port → 443  
↳ secure

HTTP = 80

HTTPS = 443

SSH = 22

## Response

↳ whatever servers response to the request you sent.

↳ Plain text

↳ HTML

↳ JSON Data (Javascript Object Notation Data)

when you scroll in  
LinkedIn server  
responses somehow in  
this way.

```
{ posts: [
  {
    creator: harkisets,
    description: "Nothing",
    reactions: {
      liked: 200
    }
  }
]
}
```

JSON Data

## Status Codes

↳ 3 digit no. to indicate outcome of client's request.

200 → OK

204 NO Content

300 → moved to new URL Per

304 → Not modified using cache version

400 → Bad Req (Invalid

system)

500 → Internal Server

401 → Unauthorized (admin)

502 error

403 → Understood req but refuses to authorize

↳ Bad gateway

404 → Not found (Not found in server)

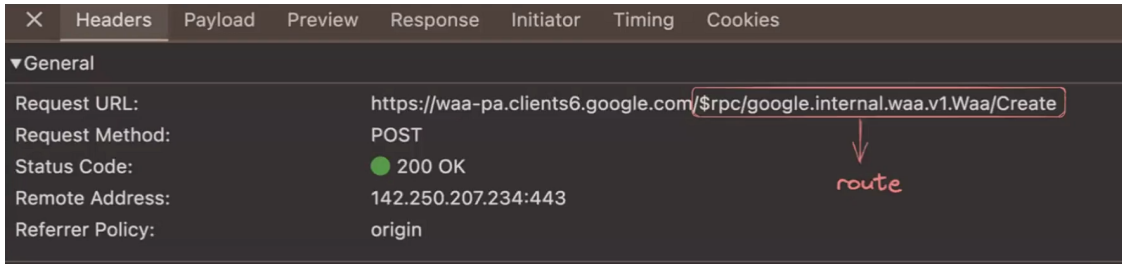

Paytm used for  
do 200 always  
body → error

# Body

↳ part of HTTP req that contain the actual data to be sent.

# Routes

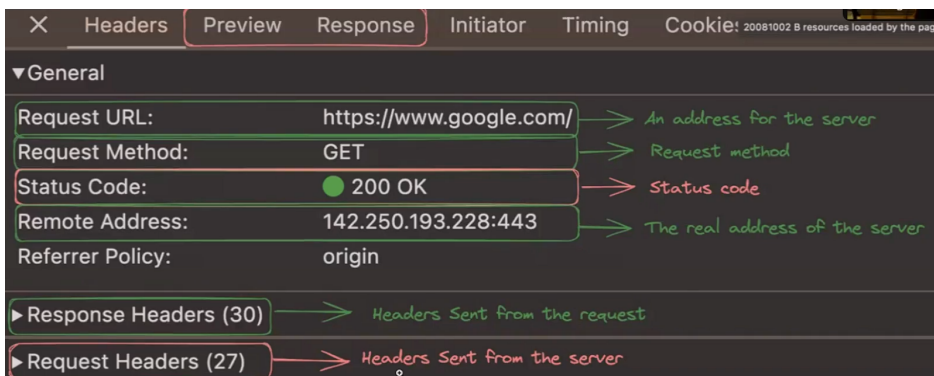

↳ what exactly you want to do

accessing  
courses

↳ /courses

↳ /calendar

http → website sends data in text  
can be taken out

https → secures that

# Async Await Syntax

```
function setTimeoutPromisified(duration) {
  return new Promise(function (resolve) {
    setTimeout(resolve, duration);
  });
}

// Promise chaining
setTimeoutPromisified(1000).then(function () {
  console.log("hi");
  return setTimeoutPromisified(3000)
}).then(function () {
  console.log("hello");
  return setTimeoutPromisified(5000)
}).then(function () {
  console.log("hi there");
});

console.log("outside the callback hell");
// promise chaining

// const sortedString = str1.split("s").sort().join("").toLowerCase();
// asd => ["a", "s", "d"] => ["a", "d", "s"] => "asd"
```

```
function setTimeoutPromisified(ms) {
  return new Promise(resolve => setTimeout(resolve, ms));
}

async function solve() {
  await setTimeoutPromisified(1000);
  console.log("hi");
  await setTimeoutPromisified(3000);
  console.log("hello");
  await setTimeoutPromisified(5000);
  console.log("hi there");
}

solve();
```

NOT stuck here

console.log("later");  
↑ same thing

Provides a way to write async code that looks and behaves like sync code make it easier to read and maintain. syntactic sugar on top of promises

O/P  
↳ later  
hi  
hello  
hi there  
{ looks like sync code but async }  
(It's a promise only)

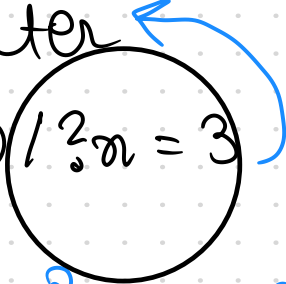

To get data dynamically

↳ localhost:3000/a/b

↳ get("/add/:a/:b", ...)

Use const a = req.params.a;

query → param

Query Parameter   
localhost:3000/?n=3

to catch this in code we

```
const n = req.query.n;
```

req → request      res → response

Middleware (1) It may or may not change the req object

(2) It will → either stop request right there  
↳ forward the req to real route handler.

↳ Ticket checker in a park

Middleware ( ) are ( ) that have access to the request object, response object and the next middleware ( ) in the application's request response cycle. The next middleware ( ) is commonly denoted by variable named next.

( ) are

↳ execute any code

↳ make changes to req and response object

↳ end the req-res cycle

↳ call the middleware ( ) in the stack.

express app is essentially a series of middleware calls.

```

const express = require("express");
const app = express();
let requestCount = 0;
function requestIncraser(req, res, next){
  requestCount+=1;
  console.log("Total number of req " + requestCount);
  next();
}
function realSumHandler(req, res){
  const a = req.query.a;
  const b = req.query.b;
  res.json({
    answer: parseInt(a)+parseInt(b)
  })
}
app.get("/sum", requestIncraser, realSumHandler);
app.listen(3000);

```

app.use(requestIncraser);  
 ↳ will be executed in every () automatically

## Common used Middlewares

↳ express.json

↳ built in middleware() in express.js used to parse incoming req bodies that are formatted as JSON.

↳ Used in PUT, POST Req

To send JSON data you need to parse the data using express or body parser.

app.use(express.json());

↳ CORS (Cross origin resource sharing)

↳ CORS origin requests by default  
 blo

It simply means that if you are on facebook.com under the hood you are not allow to access api of any other company such as hdfc.

But by default its blocked, to use it we can do it.

It a security feature that implemented by web browsers to control how resources on a web server can request on another domain.

## Headers

↳ Key value pair between a client and a server in HTTP req or res.  
They convey metadata about req, res such as → content type, auth info.

## Common headers

- ↳ Authorization (Info) → no in address
- ↳ Content type
- ↳ Referrer → url req coming from
- ↳ Cookies
- ↳ Request headers

```
// async await is just syntactical sugar for then syntax
async function getRecentPost() {
  console.log("before sending request");
  const response = await fetch("https://google.com")
  const data = await response.json();
  console.log(data);
  console.log("request has been processed")
  document.getElementById("posts").innerHTML = data.body
}

async function getRecentPost() {
  console.log("before sending request");
  await fetch("https://google.com")
  .then(function(response) {
    response.json().then(function(data) {

      console.log(data);
      console.log("request has been processed")
      document.getElementById("posts").innerHTML = data.body
    })
  })
}
```

} same as promise only

→ to convert data in json (Promise)

fetch is used under the hood to get more data like in utube as we scroll new things get added below.

Axios → used to make syntax easier

## HTTP Client

convert to json by default  
need to import module

AJAX → Async JSON and XML

## Arrow ()

```
function sum(a, b) {  
  return a + b;  
}  
  
const sum = (a, b) => {  
  return a + b;  
}  
  
app.get("/", (req, res) => {  
  
})  
  
app.get("/", function(req, res) {  
  
})
```

## map()

```
const input = [1, 2, 3, 4, 5];  
  
/// solution  
// const newArray = [];  
// for (let i = 0; i < input.length; i++) {  
//   newArray.push(input[i] * 3);  
// }  
// console.log(newArray);  
/// other solution  
function transform(i) {  
  return i * 2;  
}  
const ans = input.map(transform);  
console.log(ans);
```

## Filter()

```
const arr = [1, 2, 3, 4, 5];  
  
// ans  
function filterLogic(n) {  
  if (n % 2 == 0) {  
    return true;  
  } else {  
    return false;  
  }  
}  
  
const ans = arr.filter(filterLogic);  
console.log(ans);
```

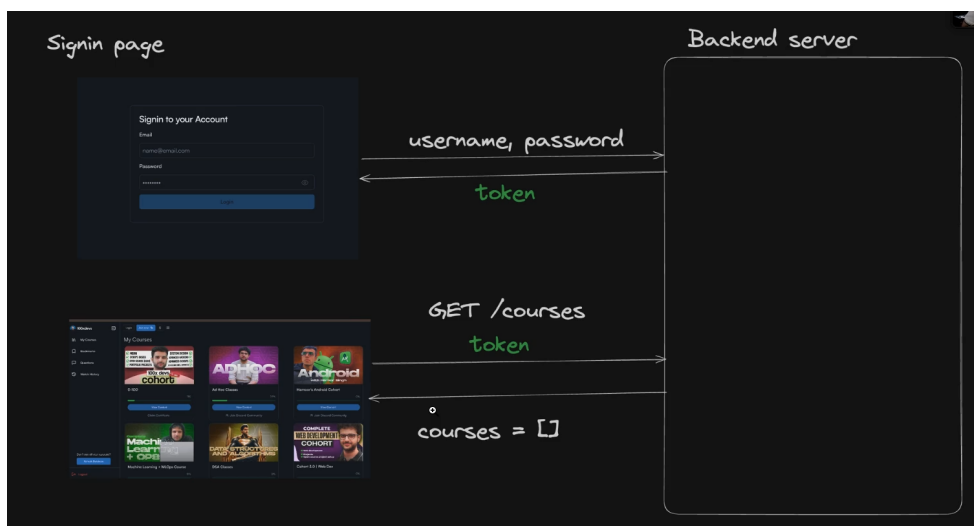

## Axios vs fetch

# Authentication

↳ Process of sign in / sign out  
making sure routes are protected and  
users can get back their own data and not  
the data from diff users.

## Things

- ↳ Auth basics
- ↳ JWT (JSON web tokens)
- ↳ Authorization header
- ↳ Creating own auth middleware
- ↳ Local storage

→ The user comes to website  
→ user sends request  
/signin with their  
username and password  
→ The user gets back a token.  
→ In every subsequent req,  
the user sends the token  
to identify it self to  
the backend.

express.json help to parse body of json file

```
function generateToken() {  
  let options = ['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l',  
    'm', 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y', 'z', 'A',  
    'B', 'C', 'D', 'E', 'F', 'G', 'H', 'I', 'J', 'K', 'L', 'M', 'N', 'O', 'P',  
    'Q', 'R', 'S', 'T', 'U', 'V', 'W', 'X', 'Y', 'Z', '0', '1', '2', '3', '4',  
    '5', '6', '7', '8', '9'];  
  
  let token = "";  
  for (let i = 0; i < 32; i++) {  
    token = token + options[Math.floor(Math.random() * options.length)];  
    //Math.random() * options.length => gives a number btw 0-42  
    //floor converts 11.3 -> 11  
  }  
  return token;  
}
```

```

for(let i=0;i<users.length;i++){
  if(users[i].username == username && users[i].password == password){
    foundUser = users[i]
  }
}
const user = users.find(function(u){
  if(u.username == username && u.password == password){
    return true;
  }
  else{
    return false;
  }
})

```

Same Same but different

What we have done

Token is set in a type of metadata in headers  
 ↳ for getting my courses

```

const express = require("express");
const app = express();
app.use(express.json());

const users=[];
//will be stored like
//[
//{username: "harkirat",password:"iloveneha",token: "afjaslkjdfsalkjas"}
//]
function generateToken() {...
}
app.post("/signup",function(req,res){ ...
})
app.post("/signin",function(req,res){ ...
})
app.get("/me",function(req,res){ ...
})

app.listen(3000);

```

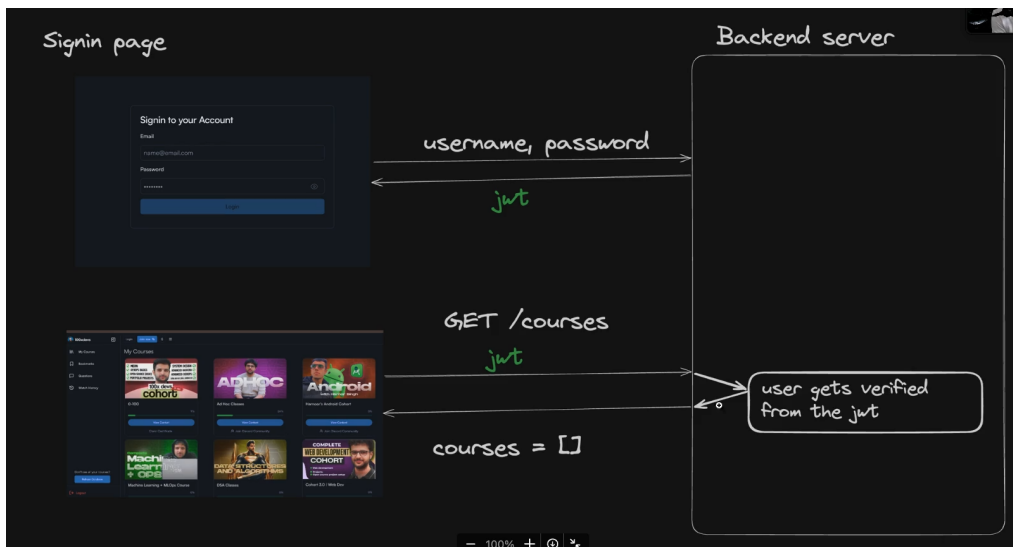

# Problem with tokens is:

To many req are sent to Databases.  
to get rid of that we use JWTs.

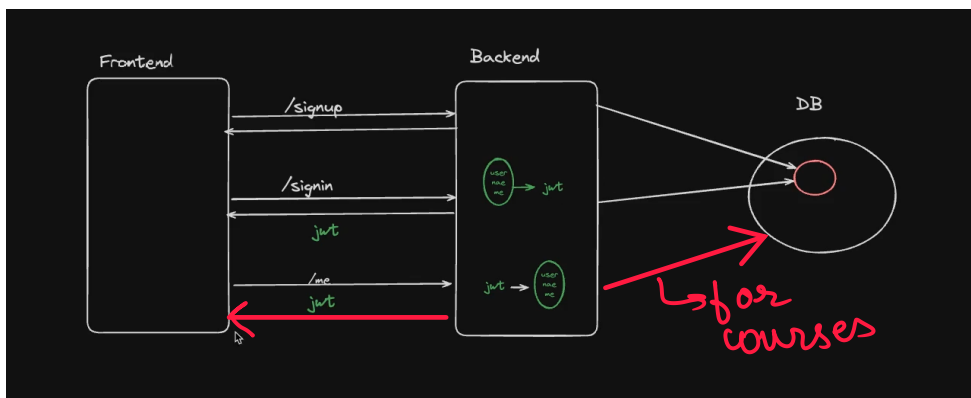

JWTs → Encrypted token which contain ID, pass  
which will help in reducing calls to DB.

↳ JWTs are stateless: contains all the info needed  
to authenticate the request, so the server doesn't  
store the session data. All data stored in token  
itself.

- DON'T want to Overwhelm the DB.
- Prevents 1 round trip from the BE server and DB for any user req.

This is the thing happening under the hood

→ If anyone has JWT means they have logged earlier so authenticated.

JWT flaw is it can be decoded on the website  
by anyone but verified by me

jwt decode → raman ko bas to encode karlega  
wahi correct mana jayega

jwt verify → It should be signed by our specific  
JWT secret not any random secret.

\_\_dirname = current direc

# Database → No SQL Databases

Earlier using NO memory DB

transient → if one goes down other works

Server should be stateless

DB must be replicated enough.

Full stack app

↳ you persist data in DB

↳ **Schemaless**

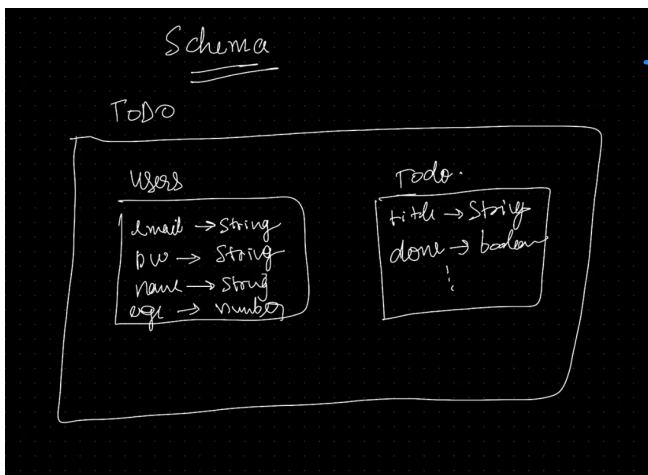

Mongo DB and NO SQL Databases

↳ Designed to handle variety of **data models** and workloads that may or may not fit neatly into tabular schema of relational db.

↳ nested structures  
↳ lectures in weeks

Properties

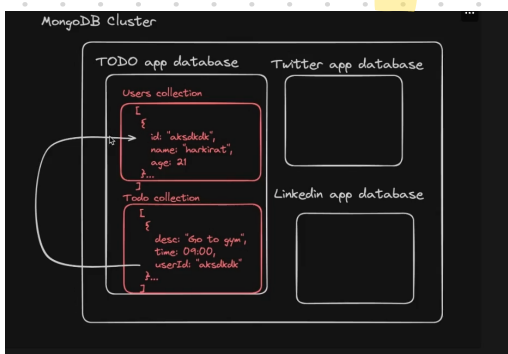

↳ **Schema flexibility** → How does the end data look like

→ Schema, SQL DB

→ But Mongo allows flexible schema, better for unstructured data

↳ **Scalability**: ↑ no. of instances, adding serv

Making different db file for more clarity.  
To use the Schema we define that

```
const User model = mongoose.model('users', User);
```

To use the file we export it also

```
module.exports = {  
  userModel: userModel;  
}
```

Model is sending request to a server very far away which means async ().

↳ Use await

We are making async. bcos while sending data it may fail to check that we need to wait which means await need to be used.

↳ Before letting user know you are logged in

for using req. body → use

↳ app.use(express.json());

All db calls must be awaited

await

↳ Wait for the process to happen before proceeding

Mongoose → requires Schema

MongoDB → NO Schema

ObjectId default provided to the user.

# Hashing is not encryption

① first we learnt jsonwebtoken

② Hashing means converting password to gibberish and storing that in db so that anytime it get leaked noone can not get password.

↳ then to check again if the password is correct just run hashing algo again and check correct or not.

## Problem

↳ If two person has same passwords then the other person can login. to fix that we use

## Salting

↳ Take the input add some random gibberish and then you hash it.

↳ Safe 😊

In DB

↳ Store → hash + random gibberish

## Bcrypt

Rainbow Table / Pre computed table

↳ Passwords with its hashings

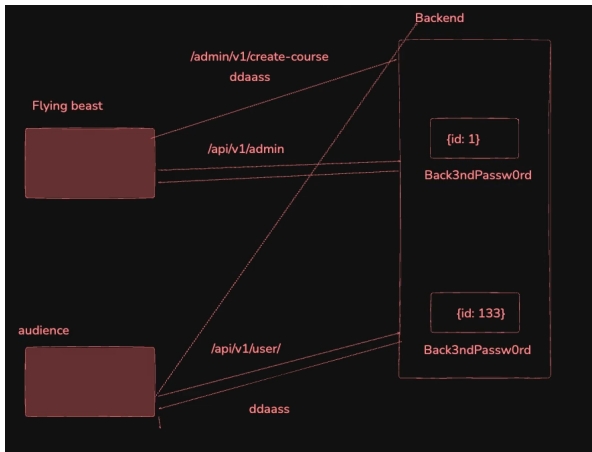

↳ Incorporates a salt and is designed to be computationally exp, making brute force attack more difficult.

# ZOD

input validation → user can send anything so we need to check that  
Schema validation ✓  
describe schema to zod

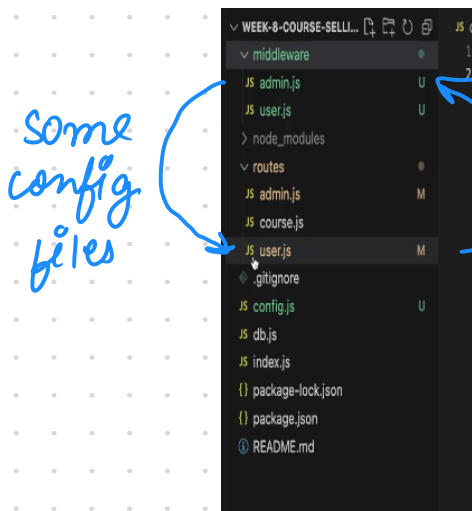

## Express Routing

user if mentioned in index.js no need to mention in the other code  
route name can be handled in index.js

Why we keep different just pass points for admin and user?

↳ To avoid users to mix admin user points

Don't get into circular dependency  
↳ means get a data from different files and giving back variables data to that file also

- `.env` → to save creds
- `.env.example` → share the schema of env file
- `.gitignore` → telling git to ignore certain files

`Dotenv` → No dependency
